Abstract: Many people have argued that the evolution of the human language faculty cannot be explained by Darwinian natural selection. Chomsky and Gould have suggested that language may have evolved as the by-product of selection for other abilities or as a consequence of as-yet unknown laws of growth and form. Others have argued that a biological specialization for grammar is incompatible with every tenet of Darwinian theory – that it shows no genetic variation, could not exist in any intermediate forms, confers no selective advantage, and would require more evolutionary time and genomic space than is available. We examine these arguments and show that they depend on inaccurate assumptions about biology or language or both. Evolutionary theory offers clear criteria for when a trait should be attributed to natural selection: complex design for some function, and the absence of alternative processes capable of explaining such complexity. Human language meets these criteria: Grammar is a complex mechanism tailored to the transmission of propositional structures through a serial interface. Autonomous and arbitrary grammatical phenomena have been offered as counterexamples to the position that language is an adaptation, but this reasoning is unsound: Communication protocols depend on arbitrary conventions that are adaptive as long as they are shared. Consequently, language acquisition in the child should systematically differ from language evolution in the species, and attempts to analogize them are misleading. Reviewing other arguments and data, we conclude that there is every reason to believe that a specialization for grammar evolved by a conventional neo-Darwinian process.

The Faculty of Language: What Is It, Who Has It, and How Did It Evolve?

Marc D. Hauser,^{1*} Noam Chomsky,² W. Tecumseh Fitch¹

We argue that an understanding of the faculty of language requires substantial interdisciplinary cooperation. We suggest how current developments in linguistics can be profitably wedded to work in evolutionary biology, anthropology, psychology, and neuroscience. We submit that a distinction should be made between the faculty of language in the broad sense (FLB) and in the narrow sense (FLN). FLB includes a sensory-motor system, a conceptual-intentional system, and the computational mechanisms for recursion, providing the capacity to generate an infinite range of expressions from a finite set of elements. We hypothesize that FLN only includes recursion and is the only uniquely human component of the faculty of language. We further argue that FLN may have evolved for reasons other than language, hence comparative studies might look for evidence of such computations outside of the domain of communication (for example, number, navigation, and social relations).

question of language evolution, and of how humans acquired the faculty of language.

In exploring the problem of language evolution, it is important to distinguish between questions concerning language as a communicative system and questions concerning the computations underlying this system, such as those underlying recursion. As we argue below, many acrimonious debates in this field have been launched by a failure to distinguish between these problems. According to one view (1), questions concerning abstract computational mechanisms are distinct from those concerning communication, the latter targeted at problems at the interface between abstract computation and both sensory-motor and conceptual-intentional interfaces. This view should not, of course, be taken as a claim against a relationship between compu-

If a martian graced our planet, it would be struck by one remarkable similarity among Earth's living creatures and a key difference. Concerning similarity, it would note that all living things are designed on the basis of highly conserved developmental systems that read an (almost) universal language encoded in DNA base pairs. As such, life is arranged hierarchically with a foundation of discrete, unblendable units (codons, and, for the most part, genes) capable of combining to create increasingly complex and virtually limitless varieties of both species and individual organisms. In contrast, it would notice the absence of a universal code of communication (Fig. 1).

If our martian naturalist were meticulous, it might note

tures; it might further note that the human faculty of language appears to be organized like the genetic code—hierarchical, generative, recursive, and virtually limitless with

Fig. 1. The animal kingdom has been designed on the basis of highly conserved developmental systems that read an almost universal language coded in DNA base pairs. This system is shown on the left in terms of a phylogenetic tree. In contrast, animals lack a common universal code of communication, indicated on the right by unconnected animal groups. What do we mean by language evolution

Haspelmath (2016)

"Thus, we now have three senses of the term “evolution” in the context of the study of languages:

(1) **origin of language** as a human-specific trait (Pinker & Bloom, and also most of McMahon & McMahon 2012)

(2) **language change** studied from the perspective of **variation and selection** (Croft 2000, etc.)

(3) language patterns and **language change at a global level** (Everett et al. and related work)

And this does not even include grammaticalization (Bybee et al. 1994)."

Methods for studying Language Evolution

Methods and approaches

“Empirical approaches to the study of language evolution”
(Fitch 2017 *Psychon Bull Rev*):

Opinion

Why Are There Different Languages? The Role of Adaptation in Linguistic Diversity

Gary Lupyan^{1,*} and Rick Dale²

Why are there different languages? A common explanation is that different languages arise from the gradual accumulation of random changes. Here, we argue that, beyond these random factors, linguistic differences, from sounds to grammars, may also reflect adaptations to different environments in which the languages are learned and used. The aspects of the environment that could shape language include the social, the physical, and the technological.

Trends

It is commonly thought that humans speak different languages simply because the languages drifted apart due to the gradual accumulation of changes.

We challenge this assumption by

Abstract

Although the quest of causation does not only concern science, it is still an important guiding principle in language research. A number of techniques developed in the last few decades opened new scenarios where testing causal relations became possible. Recent advances in information theory, time series analysis, phylogenetics, stochastic processes, dynamical systems, graphical models and Bayesian inference (among many others) set the stage for a new and exciting chapter in the field.

In parallel, in the last few decades an unprecedented amount of data became available on a large number of languages, which opened the door to a new era of cross-linguistic research. The focus on causation in the study of language is now a central topic in the study of language, and it is attracting a growing number of researchers from different disciplines.

The aim of this workshop is to address these issues, to review the state of the art, and to discuss the challenges and opportunities in the field. The workshop will provide a platform for researchers to discuss their work, to share their ideas, and to collaborate on future research.

Questions

Example questions for discussion

What are the limits of language evolution research?

What promising *new directions* are missing from this workshop?

Are we in fact "coming of age"? Does language evolution research in the near future look different from 5 years ago?

How should we approach new frontiers? Large interdisciplinary groups? Many small projects?
